

Tool Supported (Multi-Level) Language Evolution

Markus Pizka, Elmar Juergens
{pizka, juergens}@in.tum.de
Technische Universität München

Outline

Variability, Abstractions, DSLs

Case Study: DSL for product catalog CMS

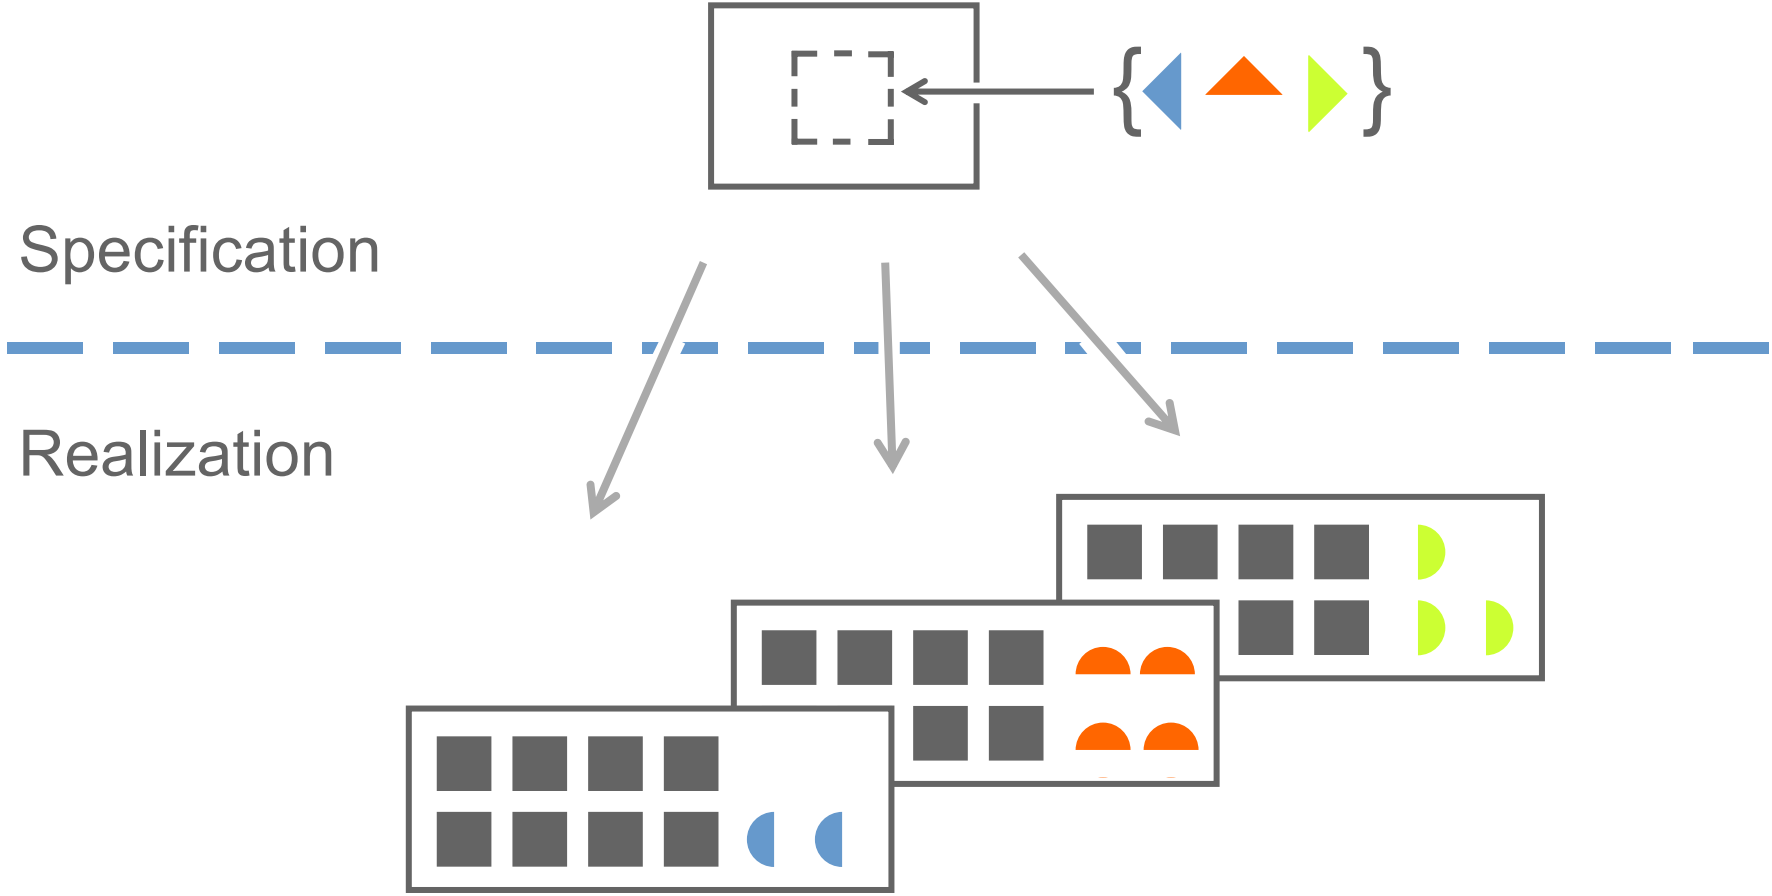

Tool Approach

Limitations & Outlook

Claim

Every abstraction mechanism deals with commonality and variability.

Abstractions and Variability

Example: GPPL

```
0:   aload_1      | 20:   getstatic    #16;
1:   astore     6 | 23:   aload_3
3:   iconst_0    | 24:   invokevirtual #22;
4:   istore     4
6:   aload      6
8:   arraylength
9:   istore     5
11:  goto      30
14:  aload      6
16:  iload      4
18:  aaload
19:  astore_3

27:  iinc     4, 1
30:  iload      4
32:  iload      5
34:  if_icmplt 14
37:  return
```

```
0:   aload_1      | 20:   new      #34;
1:   astore     6 | 23:   dup
3:   iconst_0    | 24:   aload_2
4:   istore     4 | 25:   invokestatic #36;
6:   aload      6 | 28:   invokespecial #42;
8:   arraylength | 31:   aload_3
9:   istore     5 | 32:   invokevirtual #44;
11:  goto      42 | 35:   invokevirtual #48;
14:  aload      6 | 38:   astore_2
16:  iload      4
18:  aaload
19:  astore_3

39:  iinc     4, 1
42:  iload      4
44:  iload      5
46:  if_icmplt 14
49:  return
```

Example: DSL

```
product Wrench {  
    text size;  
}
```

```
product Drill {  
    text headline;  
    text description;  
    image pic;  
}
```

```
package view.display.generated;  
  
import model.documents.generated.*;  
import view.display.Display;  
import view.display.controls.*;  
  
/** Display for Wrench documents */  
public class WrenchDisplay extends Display {  
  
    private static final long serialVersionUID = 1L;  
  
    private LabeledSingleLineTextLabel Size;  
  
    @Override  
    protected void initControls() {  
        Size = new LabeledSingleLineTextLabel();  
        Size.setLabel("Size");  
        this.add(Size);  
    }  
  
    @Override  
    public void displayDocument() {  
        Wrench doc = (Wrench) document;  
  
        Size.bind(doc.getSize());  
    }  
}
```

```
package view.display.generated;  
  
import model.documents.generated.*;  
import view.display.Display;  
import view.display.controls.*;  
  
/** Display for Drill documents */  
public class DrillDisplay extends Display {  
  
    private static final long serialVersionUID = 1L;  
  
    private LabeledSingleLineTextLabel Headline;  
    private LabeledMultiLineTextLabel ShortDescription;  
    private LabeledImageDisplay ProductImage;  
  
    @Override  
    protected void initControls() {  
        Headline = new LabeledSingleLineTextLabel();  
        Headline.setLabel("Headline");  
        this.add(Headline);  
  
        ShortDescription = new LabeledMultiLineTextLabel();  
        ShortDescription.setLabel("ShortDescription");  
        this.add(ShortDescription);  
  
        ProductImage = new LabeledImageDisplay();  
        ProductImage.setLabel("ProductImage");  
        this.add(ProductImage);  
    }  
  
    @Override  
    public void displayDocument() {  
        Drill doc = (Drill) document;  
  
        Headline.bind(doc.getHeadline());  
        ShortDescription.bind(doc.getShortDescription());  
        ProductImage.bind(doc.getProductImage());  
    }  
}
```

Invariance and Reuse

Abstraction creation aims at maximizing

- Effort saved per application of abstraction
- Number of times abstraction can be applied

Invariant parts determine both the

- Amount of reused artifacts / information

=> Amount of saved effort per use

- Amount of commonality constraints between instances

=> Number of times the abstraction can be applied

Deciding what is variable (and thus also what is invariant)
determines reuse benefit of an abstraction!

Invariance Dilemma

Increasing Invariance

- Increases saved effort per abstraction application
 - Reduces number of times it can potentially be applied
- => Conflicting Goals!

Optimal Amount of Invariance

- As much invariance as the abstraction use cases allow for
- => All use cases of the abstraction must be known
- => Not possible in practice, since future use cases are unknown!

Abstraction creation is quest for lesser evil

- Loss of potential productivity gain
- Loss of potential abstraction use cases

Claim

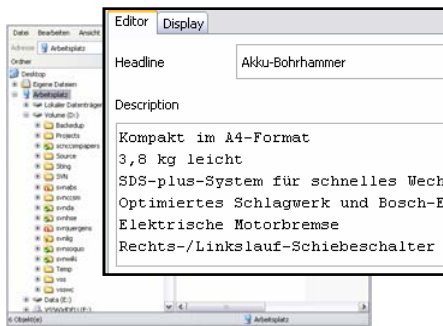

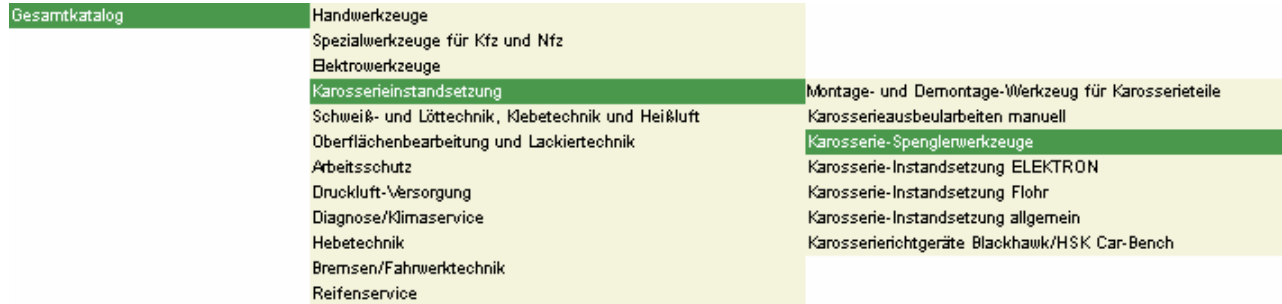

The Invariance Dilemma can be avoided by bottom-up abstraction development.

Avoiding the Dilemma

- Only consider currently known use cases
(=> ignore uncertain future uses cases)
- Make all commonalities between use cases invariants of the abstraction
=> Optimal abstraction reuse benefit
- Evolve partition between variability and invariance as new (uncovered) use cases arise

Invariance Dilemma can be avoided if the partition between variable and invariant information can change over time.

CS: Product Catalog Description Language

Catalog Description Language (2)

```
catalog {  
  document Drill {  
    field SinglelineText Headline;  
    field MultiLineText Description;  
    field MultiLineText Delivery;  
  }  
}
```

The diagram illustrates the mapping of catalog fields to UI components and a data table. Red boxes and arrows connect the fields in the code to their corresponding UI elements and table columns.

UI Components:

- Headline:** A text field in the top editor window.
- Description:** A multi-line text area in the middle editor window.
- Headline:** A text field in the bottom editor window.
- Description:** A multi-line text area in the bottom editor window.

Data Table:

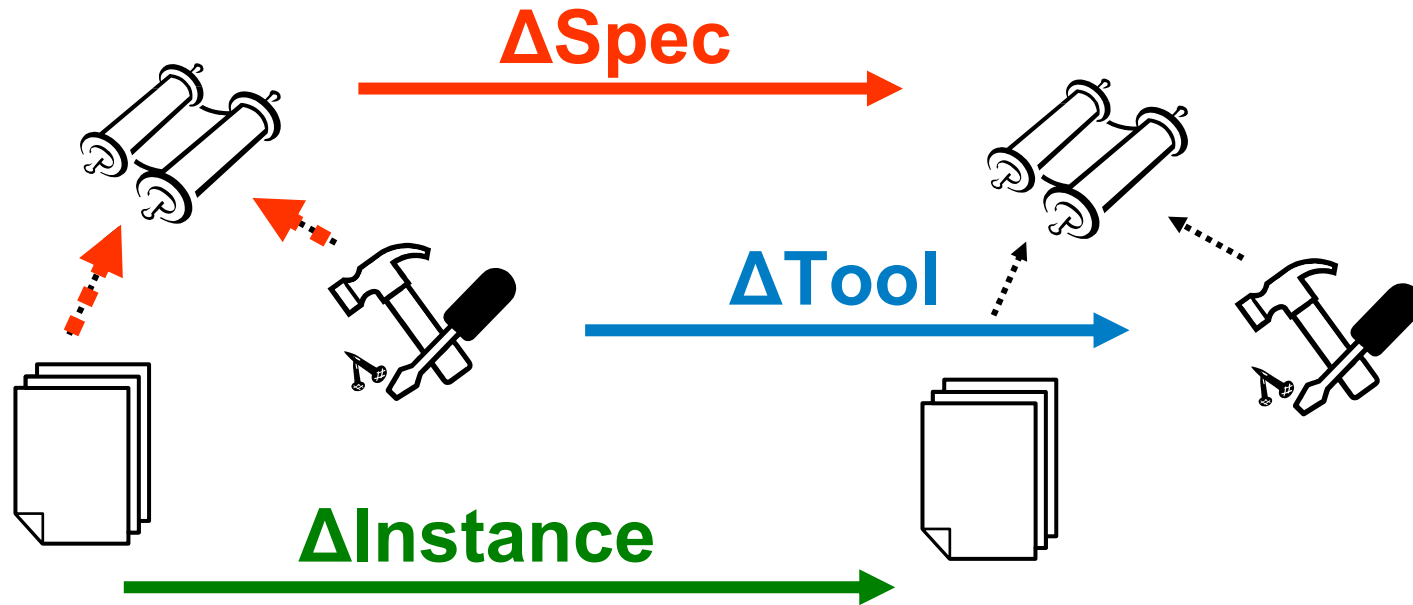

Feldname	Feldtyp
Headline	Text
Description	Memo
Delivery	Memo

Text Content:

Kompakt im A4-Format
3,8 kg leicht
SDS-plus-System für
Optimiertes Schlagwerk
Elektrische Motorbremse
Rechts-/Linkslauf-Schiebeschalter mit Einschaltsperrung

Problems with language evolution ...

Language Evolution

- Infeasible if done manually
- Compensational effort must be automated to a high degree

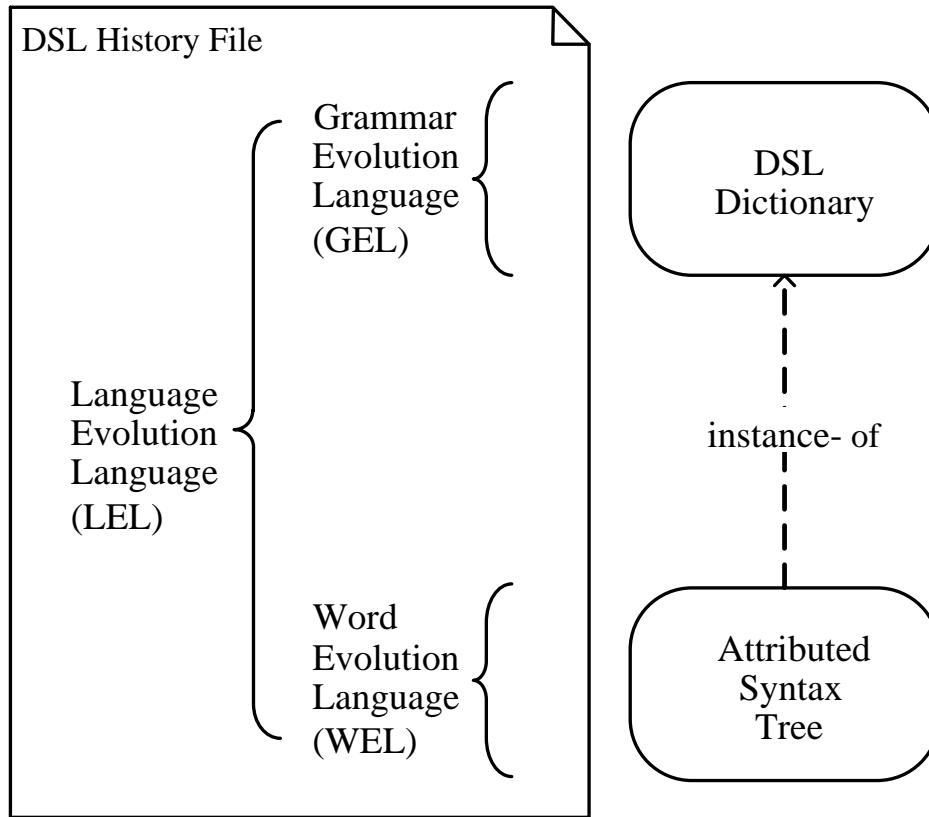

Approach

DSL History

- First version of a DSL
- Deltas btw. consecutive versions

DSL History

GEL

- DSL Dictionary manipulation
- Complete

LEL = GEL ◦ WEL

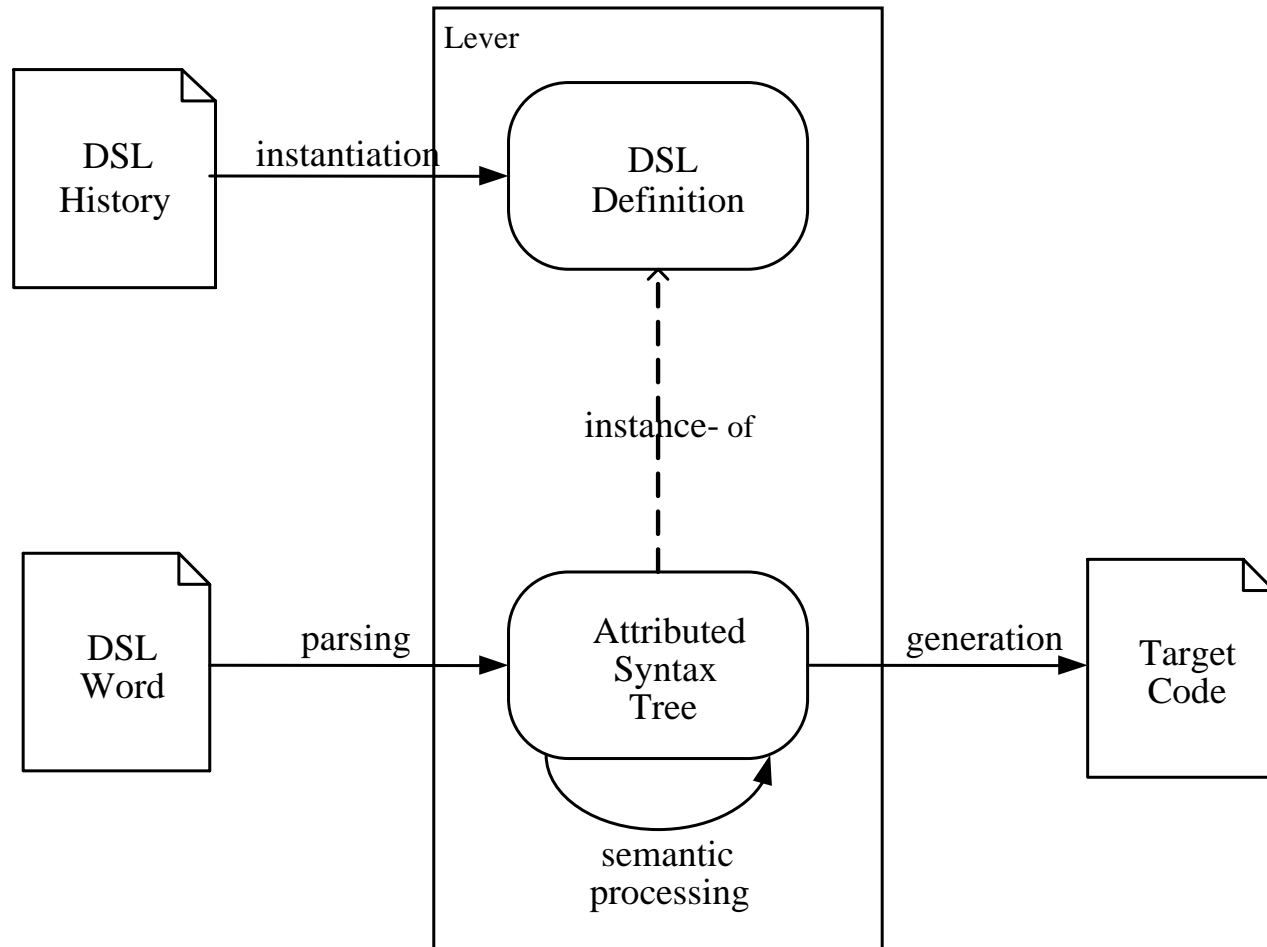

- Coupled evolution operations
- ⇒ Higher level of abstraction
⇒ Reuse

WEL

- Transformation of syntax tree
- complete, set-oriented

Language Evolver

Implementation

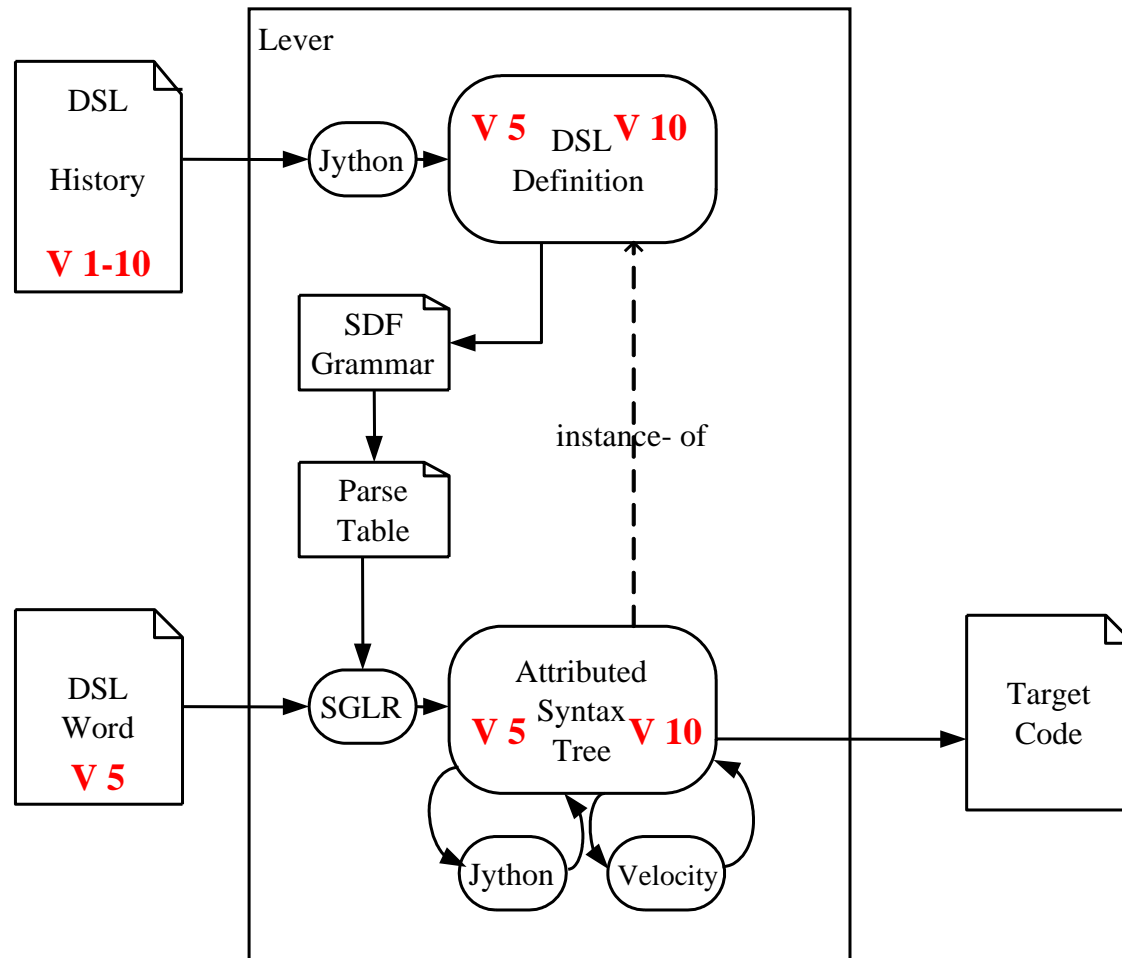

Definition Syntax and (translational) Semantics: **AXT**

- (Remote) OO- **A**tttribute Grammars
- **X**Path
- Code Generation **T**emplates

Tools / Technologies

- Parsing: *SDF* + *SGLR* (free of LL/LR like limitations)
- Code Generation: *Velocity Template Engine*
- XPath evaluation and checking: *Apache JXPath*
- Evolution languages: Internal DSLs in *Jython*

Translation Process

How could that look in practice?
Back to the case study.

CDL: Version 1

Drill {

 SinglelineText **Headline**;

 MultiLineText **Description**;

 MultiLineText **Delivery**;

}

CDL: Version 2

```
catalog {  
  document Drill {  
    field SinglelineText Headline;  
    field MultiLineText Description;  
    field MultiLineText Delivery;  
  }  
}
```

- Refactoring: Abstract syntax did not change
- Only coupled evolution operations

CDL: Version 3

```
catalog {  
  document Drill {  
    field SinglelineText Headline caption „Überschrift“;  
    field MultiLineText Description caption „Beschreibung“;  
    field MultiLineText Delivery caption „Lieferumfang“;  
  }  
}
```

- Language extension (local)
- Coupled evolution operation + manual extension of templates
- (Inserts default value for caption)

CDL: Version 4

```
catalog {  
  document Drill {  
    field SinglelineText Headline;  
    field MultiLineText Description;  
    field MultiLineText Delivery;  
  }  
  
  language german {  
    document Drill {  
      field Headline caption „Überschrift“;  
      field Description caption „Beschreibung“;  
      field Delivery caption „Lieferumfang“;  
    }  
  }  
}
```

Summary

Idea: Bottom-Up DSL construction to accommodate variability

- (Coupled) DSL evolution operations, automate
 - Adaptation of Compilers
 - Migration of existing Programs

Approach

- DSL History: contains evolution operations for all consecutive language versions
- DSL History Interpretation -> Compile programs from all versions

Limitations

Grammars (systematic)

- Well understood, few, clean concepts => Seemed simple.....
- LL/LR grammars not closed under conjunction / extension
- GLR grammars: ambiguity undecidable
- GLR parsers: bad error handling / unfriendly error messages

Limitations of Lever (our fault)

- Academic Prototype (Implementation not very forgiving)
- Limited grammar engineering tool support

Outlook

Feasibility?

- How much can really be automated?

=> Study of evolution history of 3 large industrial MMs

Formalism?

- Which tools could be better suited?

=> MetaModels instead of grammars: EMF

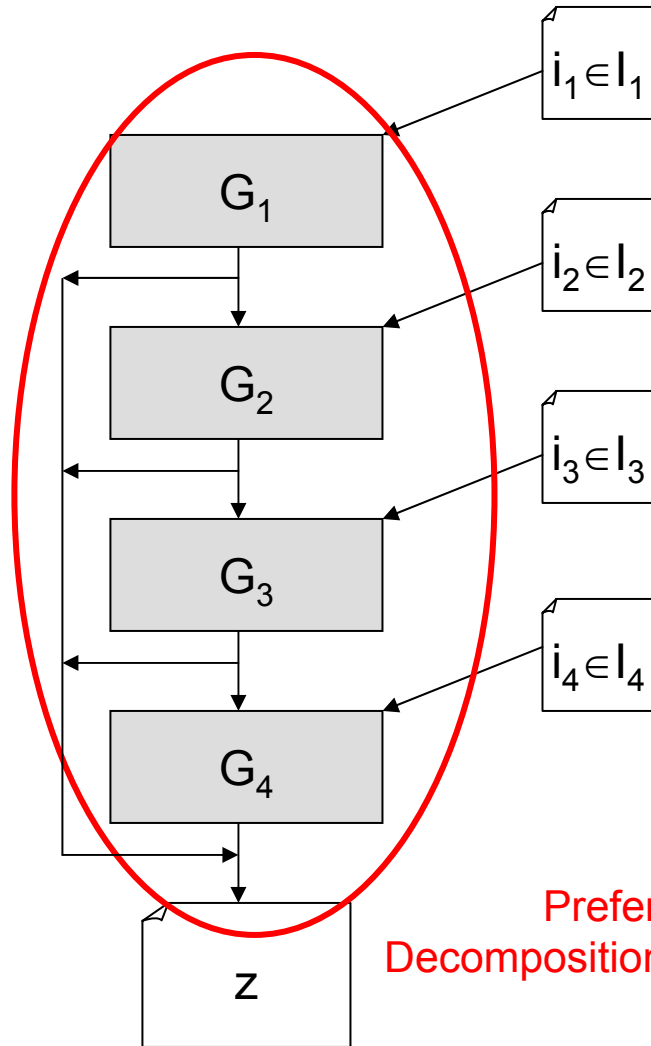

Does this really work in practice?

- Master thesis will implement CDL at company in germany

Questions?

Thank You!

Multi-Level Generation

Preferable approach
Decomposition of translation problem

=

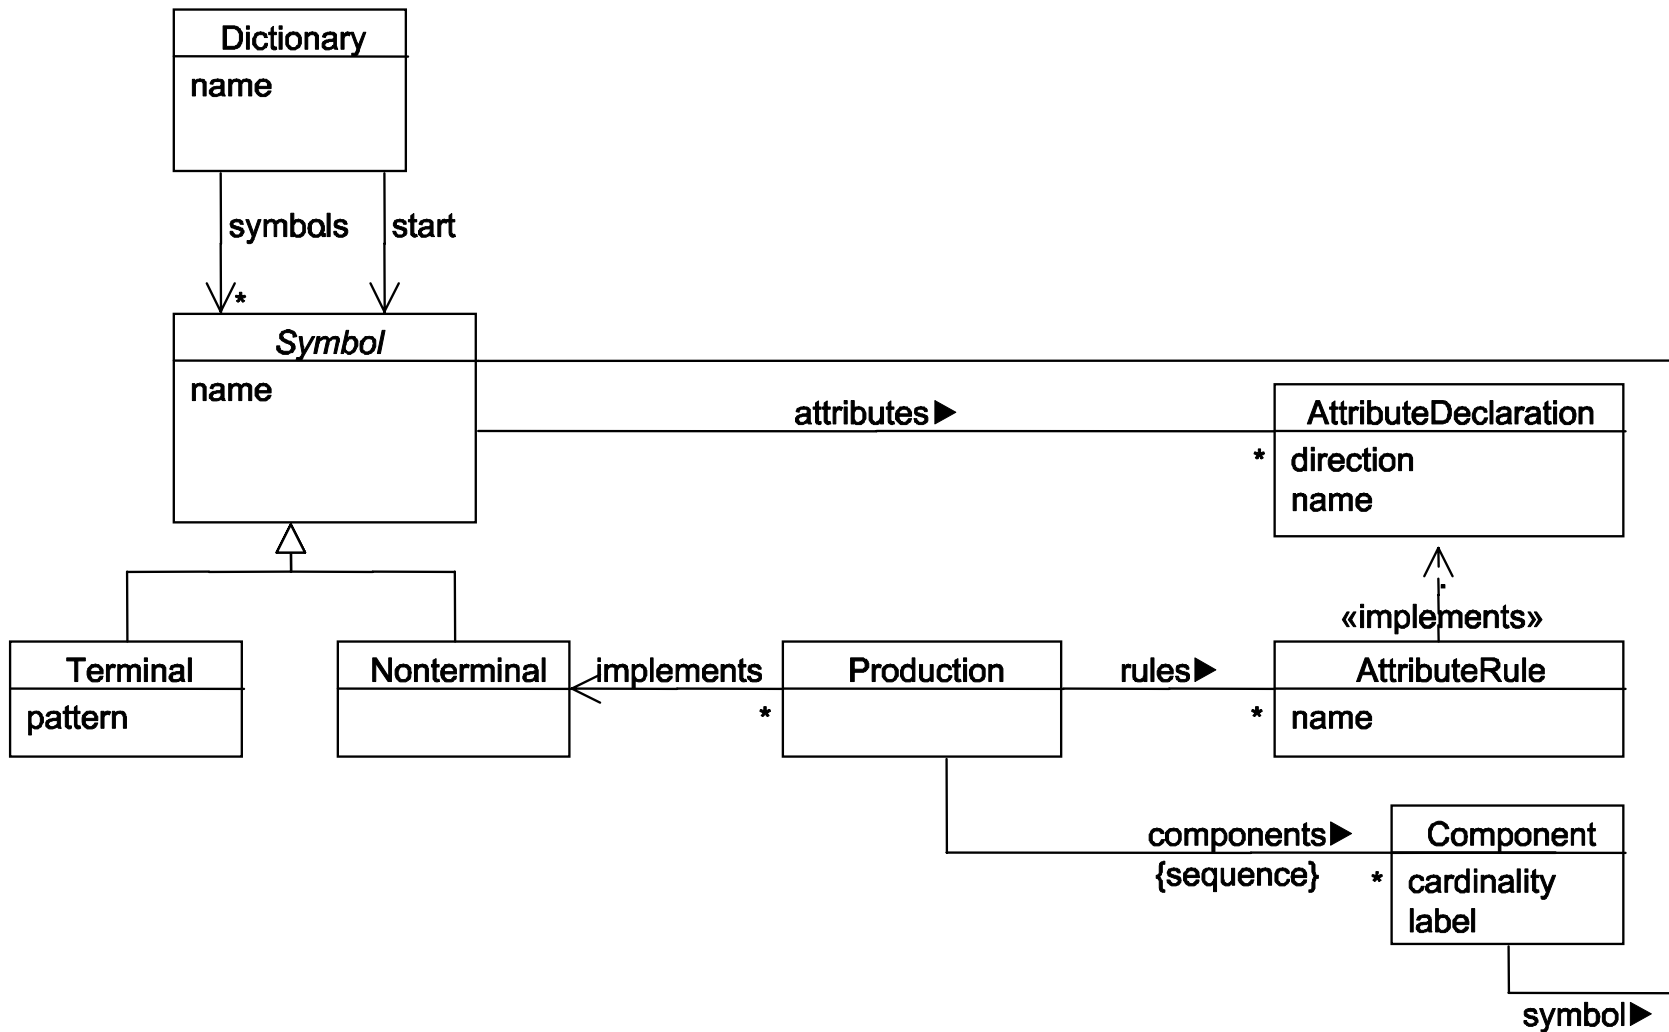

Maintenance of Multi-Level Generator

- Output of higher-level language is input of lower level lang.
⇒ Evolution on higher level potentially affects all levels beneath it.
- Change of Input language in lower level must be reflected by output language of higher level.
⇒ Evolution on lower level potentially affects levels above it.

Next goal: Check output of higher level against input of lower level. („Does generated code always compile?“)
